

```
Class C{  
    int a;  
}
```

what variables below are objects :

- a. C c;
- b. String str;
- c. Scanner scanner;
- d. int num;
- e. float f;

# Starting Out with Java: From Control Structures Through Objects

Sixth Edition

## Chapter 7

### Arrays

# Chapter Topics (1 of 2)

**7.1** Introduction to Arrays

**7.2** Processing Array Contents

**7.3** Passing Arrays as Arguments to Methods

**7.4** Some Useful Array Algorithms and Operations

**7.5** Returning Arrays from Methods

**7.6** String Arrays

**7.7** Arrays of Objects

# Chapter Topics (2 of 2)

~~7.8 The Sequential Search Algorithm~~

~~7.9 Parallel Arrays~~

**7.10** Two-Dimensional Arrays

**7.11** Arrays with Three or More Dimensions

~~7.12 The Selection Sort and the Binary Search~~

~~7.13 Command-Line Arguments~~

~~7.14 The ArrayList Class~~

# 7.1 Introduction to Arrays

- Primitive variables are designed to hold only one value at a time.
- Arrays allow us to create a collection of like values that are indexed.
- An array can store any type of data but only one type of data at a time.
- An array is a list of data elements.

# Creating Arrays (1 of 3)

- An array is an object so it needs an object reference.

```
// Declare a reference to an array that will hold integers.  
int[] numbers;
```

- The next step creates the array and assigns its address to the `numbers` variable.

```
// Create a new array that will hold 6 integers.  
numbers = new int[6];
```

0	0	0	0	0	0
index 0	index 1	index 2	index 3	index 4	index 5

Array element values are initialized to 0.

Array indexes always start at 0.

# Creating Arrays (2 of 3)

- It is possible to declare an array reference and create it in the same statement.

```
int[] numbers = new int[6];
```

- Arrays may be of any type.

```
float[] temperatures = new float[100];  
char[] letters = new char[41];  
long[] units = new long[50];  
double[] sizes = new double[1200];
```

# Creating Arrays (3 of 3)

- The array size must be a non-negative number.
- It may be a literal value, a constant, or variable.

```
final int ARRAY_SIZE = 6;  
int[] numbers = new int[ARRAY_SIZE];
```

- Once created, an array size is fixed and cannot be changed.

# Accessing the Elements of an Array

20	0	0	0	0	0
numbers[0]	numbers[1]	numbers[2]	numbers[3]	numbers[4]	numbers[5]

- An array is accessed by:
  - the reference name
  - a subscript that identifies which element in the array to access.

```
numbers [0] = 20; //pronounced "numbers sub zero"
```

# Inputting and Outputting Array Elements

- Array elements can be treated as any other variable.
- They are simply accessed by the same name and a subscript.
- See example: `ArrayDemo1.java`
- Array subscripts can be accessed using variables (such as for loop counters).
- See example: `ArrayDemo2.java`

# Bounds Checking

- Array indexes always start at zero and continue to (array length - 1).

```
int [] values = new int[10];
```

- This array would have indexes 0 through 9.
- See example: InvalidSubscript.java
- In `for` loops, it is typical to use *i*, *j*, and *k* as counting variables.
  - It might help to think of *i* as representing the word **index**.

# Off-By-One Errors

- It is very easy to be off-by-one when accessing arrays.

```
// This code has an off-by-one error.  
int[] numbers = new int[100];  
for (int i = 1; i <= 100; i++)  
    numbers[i] = 99;
```

- Here, the equal sign allows the loop to continue on to index 100, where 99 is the last index in the array.
- This code would throw an `ArrayIndexOutOfBoundsException`.

# Array Initialization

- When relatively few items need to be initialized, an initialization list can be used to initialize the array.

```
int[] days = {31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31};
```

- The numbers in the list are stored in the array in order:
  - `days[0]` is assigned 31,
  - `days[1]` is assigned 28,
  - `days[2]` is assigned 31,
  - `days[3]` is assigned 30,
  - etc.
- See example: `ArrayInitialization.java`

# Alternate Array Declaration

- Previously we showed arrays being declared:

```
int[] numbers;
```

- However, the brackets can also go here:

```
int numbers[];
```

- These are equivalent but the first style is typical.

- Multiple arrays can be declared on the same line.

```
int[] numbers, codes, scores;
```

- With the alternate notation each variable must have brackets.

```
int numbers[], codes[], scores;
```

- The `scores` variable in this instance is simply an `int` variable.

## 7.2 Processing Array Contents (1 of 2)

- Processing data in an array is the same as any other variable.

```
grossPay = hours[3] * payRate;
```

- Pre and post increment works the same:

```
int[] score = {7, 8, 9, 10, 11};  
++score[2]; // Pre-increment operation  
score[4]++; // Post-increment operation
```

- See example: `PayArray.java`

## 7.2 Processing Array Contents (2 of 2)

- Array elements can be used in relational operations:

```
if (cost[20] < cost[0])  
{  
    //statements  
}
```

- They can be used as loop conditions:

```
while (value[count] != 0)  
{  
    //statements  
}
```

# Array Length

- Arrays are objects and provide a public field named `length` that is a constant that can be tested.

```
double[] temperatures = new double[25];
```

- The length of this array is 25.
- The length of an array can be obtained via its `length` constant.

```
int size = temperatures.length;
```

- The variable `size` will contain 25.

# The Enhanced `for` Loop (1 of 2)

- Simplified array processing (read only)
- Always goes through all elements
- General format:

```
for(datatype elementVariable : array)  
    statement;
```

# The Enhanced `for` Loop (2 of 2)

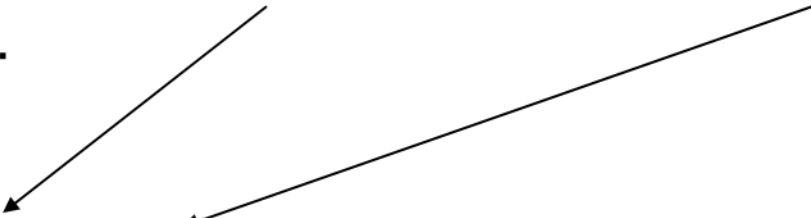

## Example:

```
int[] numbers = {3, 6, 9};  
For(int val : numbers)  
{  
    System.out.println("The next value is " +  
                        val);  
}
```

# Array Size (1 of 2)

- The `length` constant can be used in a loop to provide automatic bounding.

Index subscripts start at 0 and end at one **less than** the array length.

```
for(int i = 0; i < temperatures.length; i++)
{
    System.out.println("Temperature " + i + ": "
        + temperatures[i]);
}
```

## Array Size (2 of 2)

- You can let the user specify the size of an array:

```
int numTests;  
int[] tests;  
Scanner keyboard = new Scanner(System.in);  
System.out.print("How many tests do you have? ");  
numTests = keyboard.nextInt();  
tests = new int[numTests];
```

- See example: [DisplayTestScores.java](#)

# Reassigning Array References (1 of 3)

- An array reference can be assigned to another array of the same type.

```
// Create an array referenced by the numbers variable.  
int[] numbers = new int[10];  
// Reassign numbers to a new array.  
numbers = new int[5];
```

- If the first (10 element) array no longer has a reference to it, it will be garbage collected.

# Reassigning Array References (2 of 3)

The numbers variable holds the address of an int array.

Address

```
int[] numbers = new int[10];
```

# Reassigning Array References (3 of 3)

The numbers variable holds the address of an int array.

Address

**This array gets marked for garbage collection**

```
numbers = new int[5];
```

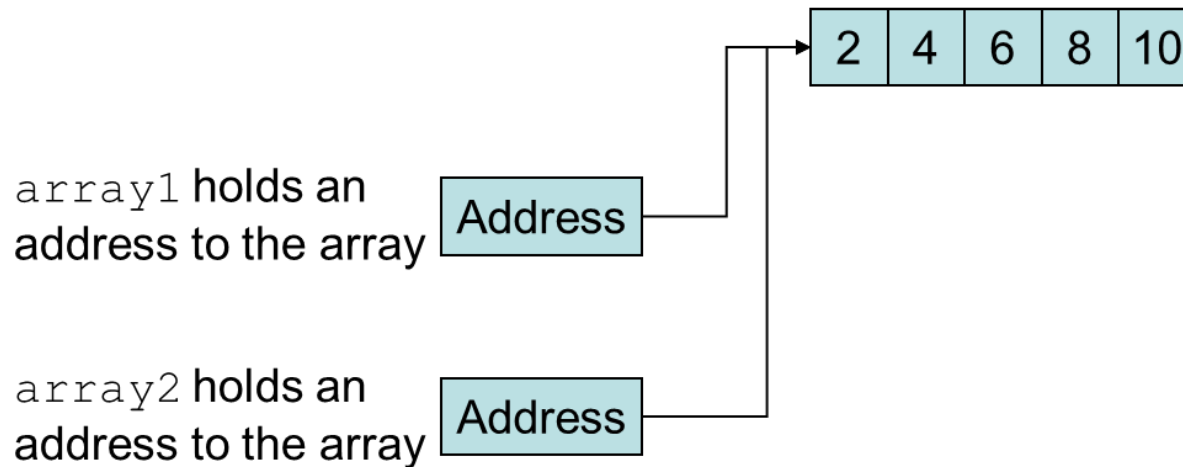

# Copying Arrays (1 of 2)

- This is **not** the way to copy an array.

```
int[] array1 = { 2, 4, 6, 8, 10 };  
int[] array2 = array1; // This does not copy array1.
```

Example: SameArray.java

# Copying Arrays (2 of 2)

- You cannot copy an array by merely assigning one reference variable to another.
- You need to copy the individual elements of one array to another.

```
int[] firstArray = {5, 10, 15, 20, 25 };  
int[] secondArray = new int[5];  
for (int i = 0; i < firstArray.length; i++)  
    secondArray[i] = firstArray[i];
```

- This code copies each element of `firstArray` to the corresponding element of `secondArray`.

# Comparing Arrays

- The `==` operator determines only whether array references point to the same array object.

```
int[] firstArray = { 5, 10, 15, 20, 25 };
int[] secondArray = { 5, 10, 15, 20, 25 };

if (firstArray == secondArray) // This is a mistake.
    System.out.println("The arrays are the same.");
else
    System.out.println("The arrays are not the same.");
```

# Comparing Arrays: Example

```
int[] firstArray = { 2, 4, 6, 8, 10 };
int[] secondArray = { 2, 4, 6, 8, 10 };
boolean arraysEqual = true;
int i = 0;

// First determine whether the arrays are the same size.
if (firstArray.length != secondArray.length)
    arraysEqual = false;

// Next determine whether the elements contain the same
data.
while (arraysEqual && i < firstArray.length)
{
    if (firstArray[i] != secondArray[i])
        arraysEqual = false;
    i++;
}

if (arraysEqual)
    System.out.println("The arrays are equal.");
else
    System.out.println("The arrays are not equal.");
```

# Useful Array Operations (1 of 2)

- Finding the Highest Value

```
int [] numbers = new int[50];
int highest = numbers[0];
for (int i = 1; i < numbers.length; i++)
{
    if (numbers[i] > highest)
        highest = numbers[i];
}
```

- Finding the Lowest Value

```
int lowest = numbers[0];
for (int i = 1; i < numbers.length; i++)
{
    if (numbers[i] < lowest)
        lowest = numbers[i];
}
```

# Useful Array Operations (2 of 2)

- **Summing Array Elements:**

```
int total = 0; // Initialize accumulator
for (int i = 0; i < units.length; i++)
    total += units[i];
```

- **Averaging Array Elements:**

```
double total = 0; // Initialize accumulator
double average; // Will hold the average
for (int i = 0; i < scores.length; i++)
    total += scores[i];
average = total / scores.length;
```

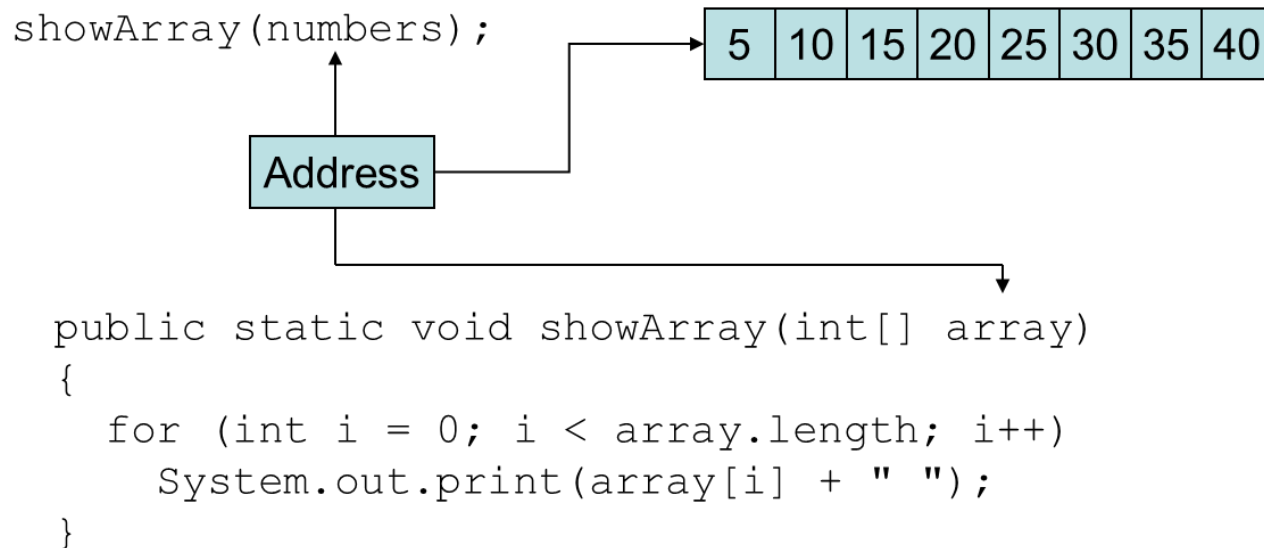

- **Example: SalesData.java, Sales.java**

# Passing Array Elements to a Method

- When a single element of an array is passed to a method it is handled like any other variable.
- See example: `PassElements.java`
- More often you will want to write methods to process array data by passing the entire array, not just one element at a time.

# Passing Arrays as Arguments

- Arrays are objects.
- Their references can be passed to methods like any other object reference variable.

Example: PassArray.java

# Returning an Array Reference

- A method can return a reference to an array.
- The return type of the method must be declared as an array of the right type.

```
public static double[] getArray()  
{  
    double[] array = { 1.2, 2.3, 4.5, 6.7, 8.9 };  
    return array;  
}
```

- The `getArray` method is a public static method that returns an array of doubles.
- See example: `ReturnArray.java`

## 7.6 String Arrays (1 of 3)

- Arrays are not limited to primitive data.
- An array of String objects can be created:

```
String[] names = { "Bill", "Susan", "Steven", "Jean" };
```

The `names` variable holds the address to the array.

A `String` array is an array of references to `String` objects.

Example: MonthDays.java

## 7.6 String Arrays (2 of 3)

- If an initialization list is not provided, the `new` keyword must be used to create the array:

```
String[] names = new String[4];
```

The `names` variable holds the address to the array.

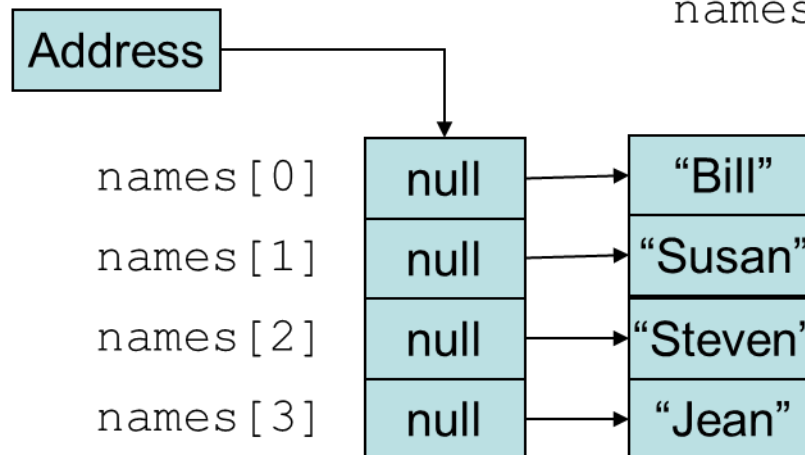

## 7.6 String Arrays (3 of 3)

- When an array is created in this manner, each element of the array must be initialized.

The `names` variable holds the address to the array.

```
names[0] = "Bill";  
names[1] = "Susan";  
names[2] = "Steven";  
names[3] = "Jean";
```

# The `length` Field & the `length` Method

- Arrays have a **final field** named `length`.
- String objects have a **method** named `length`.
- To display the length of each string held in a `String` array:

```
for (int i = 0; i < names.length; i++)  
    System.out.println(names[i].length());
```

- An array's `length` is a **field**
  - You **do not** write a set of parentheses after its name.
- A `String`'s `length` is a **method**
  - You **do** write the parentheses after the name of the `String` class's `length` method.

## 7.7 Arrays of Objects (1 of 2)

- Because Strings are objects, we know that arrays can contain objects.

```
BankAccount[] accounts = new BankAccount[5];
```

The `accounts` variable holds the address of an `BankAccount` array.

The array is an array of references to `BankAccount` objects.

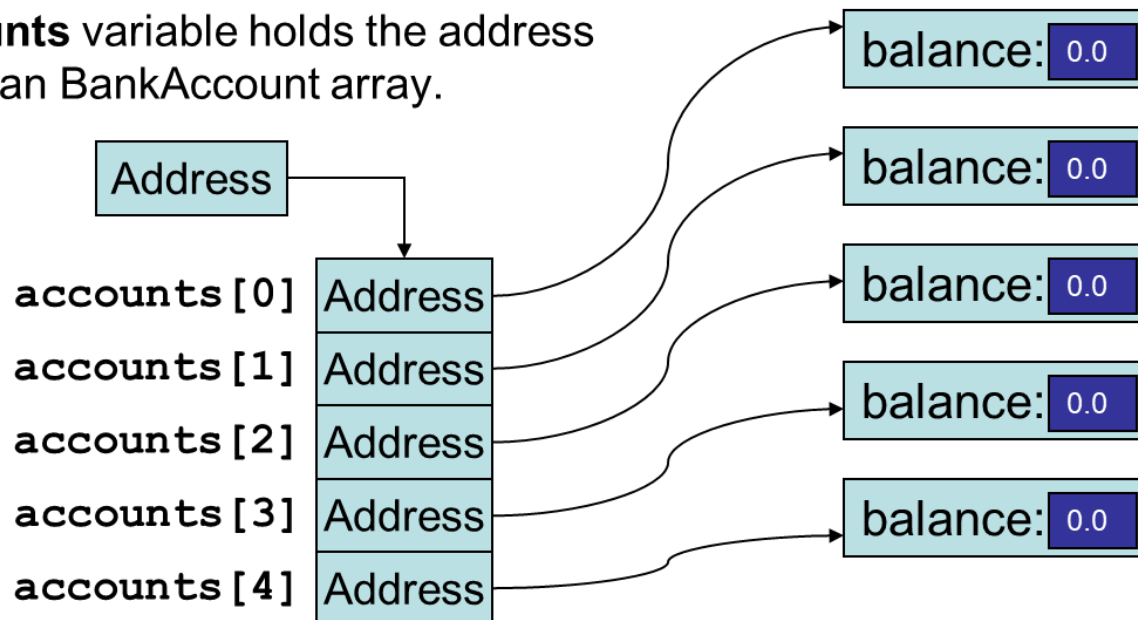

## 7.7 Arrays of Objects (2 of 2)

- Each element needs to be initialized.

```
for (int i = 0; i < accounts.length; i++)  
    accounts[i] = new BankAccount();
```

- See example: `ObjectArray.java`

The **accounts** variable holds the address of an `BankAccount` array.

## 7.10 Two-Dimensional Arrays (1 of 2)

- A two-dimensional array is an array of arrays.
- It can be thought of as having rows and columns.

	column 0	column 1	column 2	column 3
row 0				
row 1				
row 2				
row 3				

## 7.10 Two-Dimensional Arrays (2 of 2)

- Declaring a two-dimensional array requires two sets of brackets and two size declarators
  - The first one is for the number of rows
  - The second one is for the number of columns.

```
double[][] scores = new double[3][4];
```

- The two sets of brackets in the data type indicate that the scores variable will reference a two-dimensional array.
- Notice that each size declarator is enclosed in its own set of brackets.

# Accessing Two-Dimensional Array Elements (1 of 5)

- When processing the data in a two-dimensional array, each element has two subscripts:
  - one for its row and
  - another for its column.

# Accessing Two-Dimensional Array Elements (2 of 5)

The `scores` variable holds the address of a 2D array of `doubles`.

Address	column 0	column 1	column 2	column 3
row 0	<code>scores[0][0]</code>	<code>scores[0][1]</code>	<code>scores[0][2]</code>	<code>scores[0][3]</code>
row 1	<code>scores[1][0]</code>	<code>scores[1][1]</code>	<code>scores[1][2]</code>	<code>scores[1][3]</code>
row 2	<code>scores[2][0]</code>	<code>scores[2][1]</code>	<code>scores[2][2]</code>	<code>scores[2][3]</code>

# Accessing Two-Dimensional Array Elements (3 of 5)

Accessing one of the elements in a two-dimensional array requires the use of both subscripts.

The `scores` variable holds the address of a 2D array of `doubles`.

```
scores[2][1] = 95;
```

Address	column 0	column 1	column 2	column 3
row 0	0	0	0	0
row 1	0	0	0	0
row 2	0	<b>95</b>	0	0

# Accessing Two-Dimensional Array Elements (4 of 5)

- Programs that process two-dimensional arrays can do so with nested loops.
- To fill the scores array:

```
for (int row = 0; row < 3; row++)  
{  
    for (int col = 0; col < 4; col++)  
    {  
        System.out.print("Enter a score: ");  
        scores[row][col] = keyboard.nextDouble();  
    }  
}
```

Number of rows, not  
the largest subscript

Number of  
columns, not the  
largest subscript

keyboard references  
a Scanner object

# Accessing Two-Dimensional Array Elements (5 of 5)

- To print out the `scores` array:

```
for (int row = 0; row < 3; row++)  
{  
    for (int col = 0; col < 4; col++)  
    {  
        System.out.println(scores[row][col]);  
    }  
}
```

- See example: `CorpSales.java`

# Initializing a Two-Dimensional Array (1 of 2)

- Initializing a two-dimensional array requires enclosing each row's initialization list in its own set of braces.

```
int[][] numbers = { {1, 2, 3}, {4, 5, 6}, {7, 8, 9} };
```

- Java automatically creates the array and fills its elements with the initialization values.
  - row 0 {1, 2, 3}
  - row 1 {4, 5, 6}
  - row 2 {7, 8, 9}
- Declares an array with three rows and three columns.

# Initializing a Two-Dimensional Array (2 of 2)

```
int[][] numbers = {{1, 2, 3},  
                  {4, 5, 6},  
                  {7, 8, 9}};
```

The `numbers` variable holds the address of a 2D array of `int` values.

produces:

	column 0	column 1	column 2
row 0	1	2	3
row 1	4	5	6
row 2	7	8	9

# The `length` Field (1 of 2)

- Two-dimensional arrays are arrays of one-dimensional arrays.
- The `length` field of the array gives the number of rows in the array.
- Each row has a `length` constant tells how many columns is in that row.
- Each row can have a different number of columns.

# The length Field (2 of 2)

- To access the length fields of the array:

```
int[][] numbers = { { 1, 2, 3, 4 },  
                    { 5, 6, 7 },  
                    { 9, 10, 11, 12 } };
```

```
for (int row = 0; row < numbers.length; row++)  
{  
    for (int col = 0; col < numbers[row].length;  
    col++)  
        System.out.println(numbers[row][col]);  
}
```

Number of rows

Number of columns in this row.

- See example: Lengths.java

# Summing the Elements of a Two-Dimensional Array

```
int[][] numbers = { { 1, 2, 3, 4 },
                    { 5, 6, 7, 8 },
                    { 9, 10, 11, 12 } };

int total;
total = 0;
for (int row = 0; row < numbers.length; row++)
{
    for (int col = 0; col < numbers[row].length; col++)
        total += numbers[row][col];
}

System.out.println("The total is " + total);
```

# Summing the Rows of a Two-Dimensional Array

```
int[][] numbers = {{ 1, 2, 3, 4},
                   {5, 6, 7, 8},
                   {9, 10, 11, 12}};

int total;

for (int row = 0; row < numbers.length; row++)
{
    total = 0;
    for (int col = 0; col < numbers[row].length; col++)
        total += numbers[row][col];
    System.out.println("Total of row "
                       + row + " is " + total);
}
```

# Summing the Columns of a Two-Dimensional Array

```
int[][] numbers = {{1, 2, 3, 4},
                  {5, 6, 7, 8},
                  {9, 10, 11, 12}};

int total;

for (int col = 0; col < numbers[0].length; col++)
{
    total = 0;
    for (int row = 0; row < numbers.length; row++)
        total += numbers[row][col];
    System.out.println("Total of column "
                       + col + " is " + total);
}
```

# More Than Two Dimensions

- Java does not limit the number of dimensions that an array may be.
- More than three dimensions is hard to visualize, but can be useful in some programming problems.
